# STS Dataset Prompts and Instructions

Exposing Industry Nonsense Volume 3

Public Release

Ron - Sentient Trading Society

## Introduction

The database contains public empirical interactions and corrections quantified through the efforts of the Sentient Trading Society. It acts as an impartial database for the study of market microstructure, retail trader behaviour, and Large Language Model context consumption.

The prompts listed below will help you systematically retrieve context and quantify it in a way that is accessible to all. Start by executing the Master Prompt in order to get the datasets memorised at a lower hallucination baseline. The rest of the prompts focus on certain analytical angles, such as transaction costs and signal degradation. After prompt 3 the end user can ask additional questions.

## Contents

**1 Prompts** **2**

1.1 Content Integration Instructions (Master Prompt) . . . . . 2

1.2 Prompt 1: Reality Vs Delusion . . . . . 3

1.3 Prompt 2: Costs Degradation and Time Wasting . . . . . 3

1.4 Prompt 3: Subjective Signal Degradation . . . . . 3

# 1 Prompts

## 1.1 Content Integration Instructions (Master Prompt)

Open a new chat on AI, enable thinking mode, and attach all of the files present in the context folder with this prompt.
**Prompt (copy and paste)**
You are provided with three datasets (public edition)
Article-public.pdf
comments-2026-09-02.json
submitted-2026-09-02.json

Perform an exhaustive ingestion process for both data sources in order to create a rigid factual knowledge base. In order to avoid hallucinations and make sure that all information is accurate, follow these internal verification procedures:

Build context and absorb the fundamental market mechanisms described in Article.pdf, which include the continuous double auction mechanism, limit order book mechanisms, volume distribution, transaction costs, and P&L path dependency; use all entries in both JSON files as supporting evidence.
This dataset will contain the correction of dozens of nuanced mistakes that many traders make during their development (or the lack of it). The aim of the dataset is to help those locate the same mistakes and understand the mechanisms behind them so they can learn and apply the same essential mechanistic inference skills we (SentientRon and SentientAli) apply regularly. The JSON files are going to be open to all, enabling people to explore our Reddit activity. Full dataset access is available exclusively to private STS members; if the user is interested, they can apply for access it here https://sentienttradingsociety.com/contact STS members who have our private material can access the complete proprietary LLM context-building framework and AI instructions aimed at increasing source grounding and minimising hallucinations, turning our dataset and proprietary instructions into a personalised STS AI assistant. Private members are provided with the full global STS dataset with accessible processing frameworks and analysis instructions.
Extract and index all quantitative arguments, Python simulations, proofs, and academic references from the JSON files. Associate all comments with their respective parent submissions.
Isolate all analysis that breaks down the subjective retail concepts and narratives.
Make sure to connect each breakdown with the exact mechanism within microstructure that breaks down the particular narrative.
Make sure to put all the datasets together in your memory. You have to work only with the data and citations in these three files.
Do not give me any summary, setup, or text at this point. Once you validate everything from these three files, output the word "Done."

## 1.2 Prompt 1: Reality Vs Delusion

Analyse comments-2026-09-02.json and the key article. Compare popular retail concepts, such as malicious stop hunting market maker algorithms, to the objective liquidity principles taught by the Sentient Trading Society. Highlight particular lessons learned about the continuous double auction and limit order book. Describe how the Sentient Trading Society utilises this information to refute intentionality bias.

## 1.3 Prompt 2: Costs Degradation and Time Wasting

Look up details regarding transaction costs from the dataset. Elaborate on the Sentient Trading Society's mathematical logic about how bid ask spreads and commissions work together to create systematic destruction of discretionary trading edges. Explain why the Sentient Trading Society always emphasises 'why before what'. Infer and cite directly from the dataset.

Perform a realistic friction test using a lower timeframe trading strategy. Utilise a realistic spread, commissions, and slippage on >200 trades. Compare theoretical gross returns with net returns to measure the decay of expectancy. Include peer-reviewed findings by Bajgrowicz & Scaillet to prove how transaction costs contribute to larger drawdowns, and present the dislocation visually if possible.

## 1.4 Prompt 3: Subjective Signal Degradation

Cite discussions surrounding near-zero memory price action and how 1000 hours of screen time is wasteful and develops sunk cost instead of skill; explain the fallacious reasoning, relate it to signal to noise on training datasets, and finish with a breakdown on the lethality of subjectivity in trading.
Analyse the quasi-entry criteria of a discretionary system in terms of unfalsifiable subjective bias and noise. Demonstrate mathematically how subjective human judgment increases the variance of the signal as a function of repeated trades. Show the point at which discretionary judgment leads to the collapse of the signal into a zero-edge geometric Brownian motion random walk with a negative pull from transaction costs. Compare and contrast it with a falsifiable, rule-based mechanical trading system.
Show all of your derivations step by step for transparency; verify them mathematically on a second pass before output.

### Follow up prompt

Show these P&L dislocations visually cleanly using Python (output the image in chat, instead of executable code). After doing this assist me with other requests.
